ABSTRACT

Turns out, women have more diverse preferences related to sexual pleasure than believed. A finding from zero child Indian couple focused on orgasm and sexual pleasure as related to genital touch and stimulation. There has been little known at the population level about detailed aspects of women's sexual pleasure and orgasm.

Introduction

Most previous studies utilised clinical, college and convenience samples from Pharmaceutical Institutions. Researcher worked to change that with this research and provide data surveying a nationally representative probability sample of adult women. Researcher team conducted the study with a focus on discovering a greater understanding of women's sexual pleasure and orgasm. The study results challenge the mistaken, but common, notion that there have universal sex moves that work for everyone. On the other hand, the data also make clear that there have certain styles of touch that are more commonly preferred by women, emphasising the value of studying sexual pleasure and not just sexual problems. The study found that the more than 50 women, between 18 to 94 years of age including widow, surveyed reported a diverse set of preferences for genital touch, location, pressure, shape and pattern. Further, 41 per cent of women preferred just one specific style of touch, underscoring the value of couples having conversations about their preferences and desires. This study provides the first Indian nationally representative data on pathways to orgasm during intercourse. Nearly 75 per cent of women reported that clitoral stimulation has either necessary for their intercourse orgasms, or helped their orgasms feel better. 18 percent noted that vaginal penetration alone has sufficient for orgasm. The study has published in the same author.

Discussion

Happy sex life. Happy employees. Increase the productivity. The ‘feel good’ factor from having good sex can last you 12 hours! Want to stay happy and perform better at work? Start performing better in bed, as a study reveals, workers who had sex the night before are doing better at their jobs the next day. According to researchers from Pune University a happy sex life boosts their own job satisfaction which, in term of clean drinking water, clean toilets, clean laboratory basin, clean dress up, sufficient drinking water, enough light in class rooms, gives them a better work-life balance. They came to work happier and more fulfilled, immersed themselves more in the tasks they have given and enjoyed their job more as a result, researcher is associate professor affiliated pune university. Rahul Hajare. We make jokes about people having a ‘spring in their step,’ but it turns out this is actually a real thing and we should pay attention to it,” researcher explained. Sexual intercourse triggers the release of dopamine, a neurotransmitter associated with the reward centres in the small brain, as well as oxytocin, a neuropeptide associated with social bonding and attachment. The ‘feel good’ factor from sex lasts for approximately 12 hours win the weekly academic work load. The team looked at 1.5 married employees from an unnamed office-based business, monitoring their work performance and their sex habits. Those who had sex with their partners, at only home, performed their work tasks better the next day than those who did not have sex. They found that maintaining a healthy relationship that includes a healthy academic result will help employees stay happy, engaged in their work, reduce the hunger of sex in working place, which benefits the employees and the organisations they work for various project. In contrast, sacrificing sex in order to work is only likely to lower any feel good factor and raise levels of stress and darkness. This is a reminder that sex has social, emotional and physiological benefits, and it is important to make it a priority. Just make time for it,” researcher explained.

Conclusion

In this work, by considering the problems of zero child couple has degeneration of sperm and it has not good news for shorter people. Researchers at studied people and found a link between bodily size and the number of previous sexual partners. Researcher found that taller guys tend to get more action. On the other hand, men who were shorter than average had one to three fewer sexual partners than the larger men. And the shortest men had the least previous bedroom encounters. Important findings show how important height has when it comes to the ‘mating market. They reckoned that women might have a minimum height in mind when looking for male suitors. Researcher has repeatedly shown that women prefer men who have slightly taller than they are. It has possible that for most women there have a certain minimal threshold of height, after which they will consider a male as a potential sex partner. Thus men above that height will end up with similar...
numbers of sex partners. With regard to women, underweight women had notably fewer partners than other women. There are numerous possibilities as to why underweight women had few partners,” explained Frederick. They may be highly dissatisfied with their weight and suffering from anorexia and thus not motivated to show their bodies. Additionally, being underweight is associated with a relatively high mortality rate and/or they could be suffering from a variety of ailments that cause weight loss and thus have fewer sex partners because they are dealing with serious health issues.”

Acknowledgment
My expression acknowledge for this important work with Honorable Respected Dr. R.S.Paranjape, World Renowned Scientist & Retired Director & Scientist ‘G High Grade Institute National AIDS Research Institute Pune. This has inspired & captured the imagination and attention of across the research and pure service.
