

## The Mass of the Central Region of the Milky way Galaxy

Yanbikov Vil'dyan Shavkyatovich

Russian Federation

**ABSTRACT**

On the Basis of tabular values of the gravitational constant. The calculated mass of the Nucleus of the Milky Way galaxy. The numerical value of the gravitational constant is determined by the mass of the nucleus of the milky way galaxy.

**Introduction**

The galactic core determines the distribution of the gravitational constant within the galaxy. The gravitational constant is no longer constant inside the galaxy. The farther away from the center of the galaxy, the smaller it is. The mass of the Galactic core is determined in terms of the gravitational constant inside the Solar system (table value).

**The Basic Part**

Let the center of the nucleus of the galaxy O. The radius of the ball region of the galaxy is  $R_0$ . The mass of a galaxy M. The Solar system is at a distance H from the center of the galaxy (fig.1). we introduce a coordinate system. To the center of the kernel was on the z axis at a Distance H from the beginning of the coordinate system. Place a test proton in the origin of the Coordinate system at point p. In inside the ball volume.  $dV = R^2 \sin \theta d\theta d\varphi dR$ . The number of protons in one cubic meter inside the ball

$n = \frac{\rho}{m} = \frac{M}{V \cdot m}$  where V – the volume of a sphere of radius  $R_0$ , m is the mass of a proton,  $\rho$  is the density substance inside the ball, M – mass of the substance inside the bowl. The number of protons inside the volume dV is equal to  $dN = \frac{M}{V \cdot m} R^2 \sin \theta d\theta d\varphi dR$ ; where  $\Delta \varepsilon$  taken from Heisenberg's uncertainty principle:

$\Delta \varepsilon * \Delta t = \frac{h}{2\pi}$ ; Take  $\Delta t = 1$  second, then  $\Delta \varepsilon = \frac{h}{2\pi}$  The energy of the incident proton p per second from the volume dV is equal to

$\Delta \varepsilon * dN = \frac{\pi r r}{4\pi R R}$ ; where r – the radius of the proton ( $r = 1.5 * 10^{-15}$  m);  $\pi = 3.14$ . R – the distance from the volume dV before the beginning of the coordinate system. The energy of the incident proton p. 1 second of the entire volume of a sphere

$\varepsilon_p = \frac{M h r r}{8\pi m V} \iiint \sin \theta d\theta d\varphi dR$ ; where  $0 \leq \theta \leq \arctg \theta$ ,  $0 \leq \varphi \leq 2\pi$ ;

$H - R_0 \leq R \leq H + R_0$ ;  $\tg \theta = \frac{R_0}{H}$ . In view of the smallness of the angle

$\theta$  we write  $\arctg \theta = \theta = \frac{R_0}{H}$ ; In view of the smallness of the

angle  $\theta$  we write  $\arctg \theta = \theta = \frac{R_0}{H}$ ; After calculating the

integral get  $\varepsilon_p = \frac{3}{16} \frac{M h r r}{\pi m H H}$ ; Let on the edge of the Solar system. Far

away from massive objects. There are two protons at a distance R from each other. Energy falling on the p2 proton from the proton

$p_1$  is equal to  $\varepsilon = \varepsilon_p \frac{\pi r r}{4\pi R R} = \frac{3}{64} \frac{M h r r r r}{\pi m H H R R}$ ; The impulse received by

the proton p2 in one second is equal to  $\Delta p = \frac{\varepsilon}{c}$ ; The force of

attraction between the protons  $p_1$  and  $p_2$  is equal to

$F = \Delta p = \gamma \frac{m m}{R R} = \frac{3}{64} \frac{M h r r r r}{\pi m c H H R R}$ ; where c – the speed of light in

vacuum. Hence the weight of the Central region of the milky

way galaxy  $M = \frac{64}{3} \gamma \frac{\pi m m m c H H}{h r r r}$ ; where  $\gamma$  the table value of the

gravitational constant ( $\gamma = 6.672 * 10^{-11} \text{ H m}^2 \text{kr}^{-2}$ ).

Take  $H = 2.65 * 10^{20}$  m. then  $M = 1.3 * 10^{53}$  kr. Conclusion: the galactic core in the weight specifies a numeric value the gravitational constant inside the Solar system.

**The conclusions**

Calculating the mass of the galaxy's core will help advance the study of outer space.
